+ mount -t hfsplus -o ro,noatime /dev/disk2s2 /mnt/imac Executing the mount command returned an output that I believe shows the drive being mounted but is not what I am looking for: [...] 13:07:43] mount: unknown filesystem type 'hfsplus' 13:07:43] Not a valid HFS+ volume. However, the above output is not sufficient for me to understand what's going on and how to fix it. I've scoured the internet and Googled like crazy, but haven't found anything on this specific issue. The last time I was able to mount this drive successfully, the process was a bit more complicated, and I had to do it as root in order to even be able to see the drive at all. But if I do it as root (using sudo) it still doesn't work, so I know the problem is that I'm not entering the right mount command. But I don't know what that command is, since I'm not exactly sure what filesystem type my device is and how to mount it. I'm hoping there is a way to figure out what type of filesystem is being used (hfs, hfsplus, etc.). A: You may use -t hfs sudo mount -t hfs /dev/disk2s2 /mnt/imac for additional options you can see hfsplus specification at Quantification of

alpha-fetoprotein receptor levels on ovarian carcinoma cell lines. An indirect <sup>125</sup>I-labeled monoclonal antibody (MoAb) was used to assess the expression of the alpha-fetoprotein (AFP) receptor (R) on the surface of three different human ovarian carcinoma cell lines. All cell lines expressed a distinct receptor population as shown by an equilibrium binding assay and binding affinity measurements. In the presence of 0.1 M sodium chloride, the number of receptors per cell was  $3-4 \times 10^4$  while in the presence of 0.5 M sodium chloride the number increased to  $7-9 \times 10^4$ . Specific <sup>125</sup>I-labeled AFP R were located in the same membrane fractions as the cellular AFP receptors. The proportion of AFP R bound to the membrane was approximately  $3-4 \times 10^4$  per cell in 82157476af
